CHANGES IN THE RATES OF CHARGE

FOR

RAILWAY AND OTHER TRANSPORTATION SERVICES.

---

PREPARED UNDER THE DIRECTION OF

JOHN HYDE,  
*Statistician,*

BY

H. T. NEWCOMB,

*Chief of the Section of Freight Rates in the Division of Statistics.*

WASHINGTON:  
GOVERNMENT PRINTING OFFICE.  
1898.

## LETTER OF TRANSMITTAL.

---

U. S. DEPARTMENT OF AGRICULTURE,  
DIVISION OF STATISTICS,  
*Washington, D. C., April 23, 1898.*

SIR: I have the honor to transmit herewith a Report on Changes in the Rates of Charge for Railway and other Transportation Services, prepared by Mr. H. T. Newcomb, chief of the section of freight rates in this Division.

The report deals not only with the charges for the transportation of agricultural products to the principal markets and seaports, but also with those for furniture, agricultural implements, dry goods, boots and shoes, and other commodities used by the farmer, from New York to Chicago, St. Louis, and other important distributing points in the Western States and on the Pacific coast.

The report includes, in addition, tables containing certain information in regard to passenger rates. While this is of much less interest to the farmer than are the rates charged for the transportation of the products of his fields and of the commodities which he has to purchase, it constitutes no unimportant part of the transportation problem, and no justification for its inclusion need be offered.

The report, both as to passenger and freight rates, contains considerable information that is now published for the first time, and for which the thanks of the Department are due to the transportation lines by which it has been furnished.

The entire subject is treated historically, the tables in the case of some of the older railroads extending over a period of fifty years.

I respectfully recommend the publication of this comprehensive report as Bulletin No. 15, Miscellaneous Series, Division of Statistics.

Respectfully,

JOHN HYDE, *Statistician.*

The SECRETARY OF AGRICULTURE.

# CHANGES IN THE RATES OF CHARGE FOR RAILWAY AND OTHER TRANSPORTATION SERVICES.

---

## SOURCES OF INFORMATION.

The following pages contain the principal results of a study of the changes in the charges exacted for the services performed by the various carriers engaged in transporting persons and property over the more important rail, lake, river, and canal routes in the United States. Aside from the attempt to establish the averages for the years 1867 to 1887, inclusive, shown in Tables 1 and 54, which are submitted in the belief that they represent with approximate accuracy the entire railway system of the United States, and the discussion of the relation between declining prices and declining rates with which the report concludes, the work of this office has been confined to the collection, continuation, adaptation, and arrangement of data, many of which have been separately published elsewhere.

Most frequent use has been made of the report of the Committee on Finance of the United States Senate prepared by Mr. C. C. McCain, former auditor of the Interstate Commerce Commission, which was published in 1892 as part of the report on prices and wages issued by that committee and popularly known as the "Aldrich Report." Many of the tables in the present pamphlet consist of averages of rates contained in that report, data for the later years only having been gathered from original sources.

The successive numbers of Poor's Manual of Railroads, the annual reports of the statistician to the Interstate Commerce Commission, and the reports of the New York Produce Exchange, the Chicago Board of Trade, the Cincinnati Chamber of Commerce, the St. Louis Merchants' Exchange, and other commercial organizations, as well as numerous periodical publications, have all been resorted to for important material.

The generous aid of prominent officials of railway and other transportation companies has materially assisted in the collection of the data here presented, and the generally prompt and cordial compliance,

involving a considerable expenditure of time and effort on their part, with the numerous requests of this office, is most heartily appreciated. Thanks are also due to the Interstate Commerce Commission and its officers for numerous data that would not otherwise have been available; to Mr. George R. Blanchard, commissioner of the Joint Traffic Association, and Mr. C. C. McCain, commissioner of the Association of Lake Lines, for valuable assistance and suggestions. Grateful acknowledgments are extended to the foregoing and to all who furnished information or suggestions for this report.

#### CURRENCY VALUES REDUCED TO EQUIVALENTS IN GOLD.

In order to adjust all comparisons to a uniform standard and to render as historically accurate as possible not only the general tendency shown but the actual extent of the movement in accordance therewith, every figure representing a price or rate charged during the period in which the gold coin of the United States was at a premium over the various forms of currency in circulation has been reduced as nearly as possible to its equivalent in gold. Owing to the partially speculative nature of the recorded values of gold and to the inertia of prices and rates which retards their adjustment to correspond with variations in the value, as compared with the prices of other commodities and the rates for other services, of the unit of the currency by which they are measured, it is obvious that the relation between the amount of a particular payment for a commodity or a service and that which would have been exacted had gold coin continued to be the measure of prices can not be fixed with certainty.

Though this fact in no way relieves the investigator from the obligation to seek to render his results as fairly comparable as possible among themselves and with prices or rates charged at the present time, by relating them as accurately as practicable to a common standard, it imposes a second obligation to eschew obscure or complex methods of reduction which give an appearance of accuracy that, from the nature of the case, must be misleading, and to select methods so simple that the student can not only fully comprehend them but can also retrace every step of the process and, if he so desires, reproduce the original data.

In accordance with this principle, and because during the period from January 1, 1862, to September 30, 1879, the average date of the termination of the fiscal years of the railways for which data are shown was nearer to the termination of the third than to that of any other quarter of the calendar year, the means of the daily currency values of gold during the years ending with September 30 have been assumed to represent the true relation between amounts stated in currency and their equivalents in gold, and have been applied to all data for the corresponding years in Tables 1, 3, 4, 5, 7, 8, 9, 10, 56, 57, 58, 59, 60, and 61.

The average currency value of \$1 in gold during each year ending with September 30 from 1862 to 1879, inclusive, is given below:

Year.	Value.	Year.	Value.
1862.....	\$1.056	1871.....	\$1.118
1863.....	1.406	1872.....	1.120
1864.....	1.848	1873.....	1.147
1865.....	1.765	1874.....	1.108
1866.....	1.418	1875.....	1.139
1867.....	1.391	1876.....	1.131
1868.....	1.406	1877.....	1.063
1869.....	1.354	1878.....	1.014
1870.....	1.185	1879.....	1.001

To all other tables, except in a few instances to which attention is directed by footnotes, the following averages representing the value in currency of \$1 in gold during each calendar year from 1862 to 1878, inclusive, have been applied:

Year.	Value.	Year.	Value.
1862.....	\$1.133	1871.....	\$1.117
1863.....	1.452	1872.....	1.124
1864.....	2.033	1873.....	1.138
1865.....	1.573	1874.....	1.112
1866.....	1.409	1875.....	1.149
1867.....	1.382	1876.....	1.115
1868.....	1.397	1877.....	1.048
1869.....	1.330	1878.....	1.008
1870.....	1.149		

## RAILWAY FREIGHT TRAFFIC.

Table 1 shows certain averages pertaining to the volume of freight traffic and to the revenue derived therefrom, which, together with similar averages relating to the transportation of passengers, constitute the principal original matter of this report. The Bureau of Statistics of the Interstate Commerce Commission was organized during 1888, and has subsequently collected statistics which are comparable with those for the earlier years shown in the table, and it was therefore considered unnecessary to bring this portion of the work of this office down to a later year than 1888. Through the courtesy of the Interstate Commerce Commission, it has been possible to complete the table by the inclusion of some averages obtained from the records of that office that have not been published heretofore, as well as those from its annual reports.

TABLE 1.—*Volume of traffic, efficiency of service, and earnings.*

Year.	Average number of tons carried per mile of road operated.	Average number of tons carried 1 mile per mile of road operated.	Average mileage of freight trains per mile of road operated. 1895.....	3.919	479,490	2,622	1.55	189.69	122.32	4,106.94	1.60.300	1.05.846	.839
1896.....	4.208	523,832	2,720	1.60	198.81	124.47	4,322.48	1.62.553	1.03.378	.806

In order to establish the averages of Table 1, data were collected and tabulated showing the number of miles of railway worked, the number of tons of freight carried, the number of tons of freight carried 1 mile, the number of miles run by freight trains, and the gross earnings from freight service for every railway relating to which all or any portion of the desired information could be obtained, and comparisons were made among the totals representing the aggregates of these items for each year, after carefully excluding in each case every railway for which both the items from the aggregates of which the average was to be obtained had not been secured.

For example, it was ascertained that during 1882 several hundred railways performed services in the movement of freight which were equivalent to carrying 37,687,815,702 tons 1 mile, and it was also found that a still greater number of railways collected \$456,978,581 as compensation for the transportation of commodities. Obviously, an accurate average rate per ton per mile could not be obtained by dividing the latter by the former amount. Such an operation would give an apparent rate of 1.213 cents, which is considerably higher than the actual rate, 1.102 cents, the latter result being obtained by deducting 9,821,525 ton-miles, for which the revenue could not be obtained and \$41,852,320 of revenue from freight collected by railways for which the aggregate freight movement could not be ascertained.

As is generally known, there was not, prior to the passage of the interstate-commerce law, any substantial uniformity in the beginning and ending of the fiscal years of different railway corporations. The averages in the table do not, therefore, represent any definite period of twelve months, but each has been obtained from a series of items relating to different periods, all terminating within the calendar year. As the object of this investigation was to ascertain whether there had been any marked tendency toward higher or lower charges for transportation and to afford means for an approximate estimate of the importance of any such tendency, if discovered, rather than to establish an exact and unimpeachable average of the charges paid within any definite period, the uncertainty in regard to the time represented by the various averages does not materially affect their value.

The following table, showing the mileage of the railways whose fiscal years terminated on each of the particular dates shown within the calendar year 1882, presents facts which are fairly representative of the years prior to 1887. The efforts of the statistician of the Interstate Commerce Commission have since that date resulted in securing very desirable uniformity in the periods covered by the annual reports of nearly all interstate railways.

Twelve months ending with—	Miles.	Per cent.	Twelve months ending with—	Miles.	Per cent.
January 31 .....	14	0.01	September 30 .....	14,602	14.98
March 31 .....	3,411	3.50	October 31 .....	473	.49
April 30 .....	13	.01	November 30 .....	1,572	1.61
May 31 .....	3,118	3.20	December 31 .....	61,525	63.12
June 30 .....	10,864	11.15	Unknown .....	301	.31
July 31 .....	559	.57			
August 31 .....	1,018	1.05	Total .....	97,470	100.00

It is important to consider to what extent the averages in Table 1 may be accepted as representing the total mileage of all of the railways which were in operation in the United States during the years to which they relate. The following table shows the number of miles operated during each year, from 1867 to 1887, inclusive, and the proportion of such mileage represented by each of the averages in the first table:

TABLE 2.—Per cent of the railway mileage of the United States represented by averages under similar headings in Table 1.

Year.	Number of miles operated.	Average number of tons carried per mile of road operated.	Average number of tons carried 1 mile per mile of road operated.	Average mileage of freight trains per mile of road operated.	Average number of tons carried per mile run by freight trains.	Average number of tons carried 1 mile per mile run by freight trains.	Average distance carried per ton.	Average revenue from freight per mile of road operated.	Average revenue from freight per mile run by freight trains.	Average revenue from freight per ton carried.	Average revenue from freight per ton per mile carried.

All further consideration of the averages in Table 1 should take into account the facts in the foregoing table, from which it appears, among other things, that none of those averages represents less than one-eighth of the railway mileage in operation during the period to which it relates; that all save one represent more than one-fifth of such mileage, and that subsequent to the year 1868 more than one-third is invariably represented. The possibility of collecting more complete information for the later years shown, is attributable, not so much to the destruction, owing to the lapse of time, of the records of the earlier years, as it is to the progressive improvement in methods of railway accounting, which, while due in some measure to the requirements of regulative legislation, is, in a larger degree, a consequence of the increasing importance assigned to statistics of the results of the operations of railway properties by the most practical and competent among railway officials and by the investing public. This is particularly to be observed in connection with the means of measuring the services performed in the movement of property by establishing the ton moved 1 mile as the unit of freight services and reducing all transportation of commodities to that basis.

The second column of Table 1 shows the average density of traffic, the figures having been obtained by dividing the number of ton miles representing the total transportation of each year by the total mileage operated by the companies performing that transportation. Glancing at the column similarly headed in Table 2, it will be seen that it has been possible to collect data from which to derive this average from a much larger percentage of the railways of the country in the later than in the earlier years. This leads to a comment upon the figures in Table 1 which is obviously applicable to many of the data it contains.

It is a fact which may be verified, as well as one which would be naturally presumed, that the railways earliest to adopt accounting methods that make it possible to secure statistics which, though formerly neglected, are now almost universally considered essential to that knowledge of the conditions of railway business which must necessarily be preliminary to good management, were those operating more than the average mileage, receiving more than the average amount of traffic per mile of line, and, consequently, able to conduct their operations with lower relative expenditures and likely to charge lower rates.

It may be presumed also that the securities of such companies would be more highly considered by investors and that the payments upon their bonded indebtedness, i. e., their fixed charges, would have been at a rate somewhat lower than the average. The practical application of these considerations to the data in the second column of Table 1, is, that the volume of traffic upon the railways of the United States has not increased merely from 279,712 ton miles per mile of road operated in 1867 to 523,832 ton miles in 1896, or slightly less than 100 per cent, but that the average shown for the earlier year, which represents approximately 42 per cent of the mileage operated during that year, relates to those railways having at that time the greatest density of traffic, and that the actual average for the entire country is likely to have been considerably less. Properly understood, therefore, the column under consideration shows the minimum increase in traffic that may reasonably be assumed to have taken place.

The first column of Table 1 shows the average tonnage carried per mile of railway-operated during each year. In order correctly to understand these or any other averages that are controlled by the aggregate freight tonnage, it is necessary that allowance should be made for the fact that any total obtained by adding the tonnage of different roads is likely to contain some duplication on account of identical shipments, which, traversing two or more roads between their respective points of origin and of destination, are counted once for each company over the road of which they pass.

The consolidation of connecting lines, characteristic of the first decade after the war for the preservation of the Union, must, to some extent, have reduced the aggregate duplication due to this cause, and

its effect should be added to that of the heavier traffic heretofore alluded to, of the lines in relation to which it was possible to secure information for the earlier years in estimating the accuracy of these figures. The averages in the following column are, however, those which most accurately measure the services performed in the transportation of freight, and they are fortunately not subject to any similar element of error. The actual increase in the volume of traffic per mile of line is, for the reasons heretofore stated, believed to have been greater than is indicated by the actual figures.

The absence of any substantial change in the relation between the number of miles operated and the distance traversed by freight trains is probably due to the fact that the freight-train mile, which is made the unit for this purpose, has undergone considerable transformation. The general use of larger locomotives has led to a considerable increase in the average number of cars in each train, which has been accompanied by a notable tendency to substitute larger cars for those which, in the natural course of business, have to be replaced, thus increasing very materially the efficiency of the train as a machine for moving commodities. This is to some extent supported by the figures showing the average number of tons carried per mile run by freight trains, which has increased from 0.867 of 1 ton in 1867 to 1.312 tons in 1887, though the accuracy of this measure is impaired by the limitations referred to in relation to the averages in the first column.

No such difficulty is met with in studying the facts presented in the column headed "Average number of tons carried 1 mile per mile run by freight trains." These averages are based upon the most satisfactory measure of freight transportation available and represent the actual average number of tons in each train per mile run, or, in other words, at any particular instant of time. The increase shown from 81 tons in 1867 to 111 in 1877, 155 in 1887, and 199 in 1896, measures with considerable accuracy the actual increase in the efficiency of train service, which has made it possible to perform twice as much transportation per mile of line as in 1867 without increasing train mileage.

The averages representing distance carried per ton have some value as showing the average length of haul by separate carriers, but must not be understood as intended to show the average number of miles traversed by each shipment. They are affected by the duplication previously referred to in the aggregate tonnage, while the consolidation of connecting lines tends to produce an apparent increase that is not due to any real change in commercial movement. Though the development of the western portion of the country has unquestionably tended to raise the average distance which freight is moved, the growth of local business has operated in an opposite direction and it is quite impossible, with the data now available, to determine the net result.

The effect of declining railway charges is perceived in the averages representing the gross revenue from freight service per mile of road. Even though it is probable that the roads of greater earning capacity

are more heavily represented during the earlier years, the fact that an increasing volume of traffic has been accompanied by a decreasing volume of earnings can not fail to be significant. The comparatively slight increase in earnings from freight per mile run by freight trains, when considered in connection with the great increase in the efficiency of such trains, shows that the benefits of improved facilities and methods have not been wholly absorbed by railway corporations.

The data in the column headed "Average revenue from freight per ton carried" are believed to be of considerable value in spite of their failure to represent, for reasons heretofore explained, the actual average payment for the transportation of each shipment. They can profitably be compared with other averages controlled by the same unit, particularly with that representing the distance carried, and thus be made to indicate, though they can not measure, the decline in charges for railway services.

The figures in the last column of Table 1 are unquestionably the most important in the entire report. They represent the average amount received for the transportation of each ton of freight for each mile of its movement. Besides relating to the most satisfactory unit in accordance with which transportation services can be measured, the rate per ton per mile is an especially desirable measure of changes in freight charges from period to period, because, unlike published schedules of rates, which in earlier years were deviated from so frequently as to render them in many instances of but the slightest value as showing the actual charges, the rate per ton per mile takes account of all concessions from published charges except in those instances, it is impossible to say how frequent, in which rebates were charged as operating expenses.

When representing the entire traffic of a region or a railway, the rate per ton per mile has the further advantage that it is based upon data which include local as well as through traffic, and consequently, that it does not give the undue prominence to rates which are made under conditions of competition, which is sometimes observed in comparisons of the rates applied to particular commodities or classes of traffic. The averages under consideration are qualified by the fact that those for the later years include all railways, while only such roads as had adopted advanced methods of accounting, i. e., the roads of greatest traffic and lowest rates, could be included for the earlier years. The decline, which is seen to have been comparatively regular from nearly 2 cents per ton per mile, in 1867, to about 8 mills in 1896, amounts to about 60 per cent, and is probably not exceeded by that in the price of any important commodity among those largely shipped by rail. It should be borne in mind, in connection with this, that all of the amounts in the last four columns of Table 1 are upon a gold basis.

Table 3 contains average rates per ton of freight per mile for each of a large number of railways, and has been made to cover the longest period with regard to each company included for which the data

required could be secured from any reliable source. Railways which have passed through the processes of reorganization have been traced through the earlier years under their former names and, where the corporation now in existence is the result of the consolidation of two or more companies, data for the most important of the constituent companies have been inserted wherever practicable. The study of this table will be more profitable to those who are acquainted with the development of the railways included, or who have access to information relating to their growth, whether by the construction of new lines or the absorption of those already in existence.

An instance in which such knowledge would be almost essential would exist should a railway traversing a densely populated and prosperous region extend its lines into a region sparsely settled and offering little traffic. Naturally, rates applicable to traffic over the newer portion of the road would be higher per ton per mile than those formerly collected and would increase to some extent the average for the entire road, although no actual increase in charges would have occurred. The greater number of the averages relating to the years prior to 1888 have been obtained from data furnished directly to this office by officials of the railways the business of which they represent, but no source of accurate information has been neglected. With the exception of a very few lines whose operations are reported to the Interstate Commerce Commission as part of those of the systems in which they are included, the averages shown in the reports of railway statistics prepared by the statistician to the commission, have been inserted for the years 1888 to 1896, inclusive. Through the courtesy of the commission this office is able to publish similar averages for the year 1897, obtained from the reports of the railways in advance of their publication by that office. The arrangement of the railways shown in geographical order, though manifestly desirable, was not considered of sufficient importance to justify the use of the extra space that it would have required.

TABLE 3.—Average rates per ton per mile, in cents.

a One month ending July 31, 1894; merged in Southern Railway.

Table 10 shows the average rates per ton per mile collected for the transportation of coal by the companies which make public separate data relating to such traffic. The ton used is one of 2,000 pounds, in order to make the averages comparable with those for other traffic. During the period from 1878 to 1887, inclusive, for which no averages are shown for the Central Railroad of New Jersey, that company was under lease to the Lehigh Valley Railroad, and the averages for the latter represent the traffic of both lines.

*a* Leased to Lehigh Valley Railroad.*b* Leased to Illinois Central Railroad.

The averages shown in Tables 11 to 52, inclusive, have been obtained by multiplying each rate by the number of days during which it was in effect and dividing the sum of the products so obtained by the number of days in the year or other period represented. The adoption of this method is equivalent to the assumption that equal quantities of the commodities included go forward daily. This method, while not entirely satisfactory, is probably the best which can be adopted, owing to the absence of available records showing the quantities of each commodity shipped during the prevalence of each rate.

The tendency of shipments to concentrate during periods of low rates might be supposed to render averages obtained in the manner described somewhat too high, although this tendency may have been offset by the comparative steadiness of the demand for the commodities which constitute the principal items of westward-bound traffic. Another element of error in the tables under consideration arises from their having been derived mainly from published schedules of charges and from the frequency with which such schedules were formerly deviated from in order to secure business that might otherwise seek rival routes. Only general allowance can be made for the error so caused, since the actual rates charged were known to but few individuals at any time, and data

from which to estimate with any degree of accuracy the extent of the concessions from the schedules from time to time established, which were made to shippers, are now wholly lacking.

Rates from New York to Buffalo are illustrative of those from all northern Atlantic seaboard cities and adjacent territory to Buffalo and the other trunk-line termini, including Erie, Pittsburg, and Wheeling. While rates to and from these points have not always been identical with those from New York to Buffalo, they have generally varied in substantially similar proportions.

TABLE 11.—*Miscellaneous commodities—average rates, regardless of quantity shipped, in cents per 100 pounds.*

The importance of the averages shown in Tables 14, 15, and 16 is not due wholly to the fact that New York and Chicago are the most populous among American cities, nor is it attributable solely to their commercial importance as distributing centers or as gateways through which trade seeks access to regions rich in agricultural resources or abounding in manufacturing industries. While each of these facts would entitle such rates to be given great weight in studying the trend of railway charges, some knowledge of the rate-making practices followed by the great trunk railways is essential to a full appreciation of the relation of rates between New York and Chicago to railway rates generally. The cities in question are made basic points for the adjustment of charges on the vast traffic exchanged among the railways serving that portion of the United States which is situated north of the Potomac and Ohio rivers and east of the Mississippi River. Any change in the rates between New York and Chicago consequently causes corresponding changes in the charges for every through shipment of similar commodities in the region indicated, and rates on through shipments which originate at most points east of Lake Michigan and are destined westward to trans-Mississippi points east of the Pacific coast are also affected.

A brief explanation of the system of which this is a consequence may be of value. Supposing all westward shipments originating east of a line drawn from Toronto, Ontario, to Huntington, W. Va., through Buffalo, Salamanca, Pittsburg, Wheeling, and Parkersburg to commence at New York, the rates from the latter city to Chicago are considered as 100 per cent, and those to any other city or town west of the line indicated and east of the west bank of the Mississippi River are fixed at certain percentages of these bases.

For example, the amount charged upon any shipment from New York to Cleveland, Ohio, is 71 per cent of that which would be collected on an equal quantity of the same commodity shipped from New York to Chicago. Shipments to Toledo are charged for at the rate of 78 per cent of the New York to Chicago charge; to Detroit, 78 per cent; to Cincinnati, 87 per cent; to Indianapolis, 93 per cent; to Peoria, Ill., 110 per cent, and to Rock Island and East St. Louis, Ill., 122 per cent. When shipments originate at points other than New York east of the line from Toronto to Huntington, and are destined westward to points beyond it, the rates from New York to destination are ascertained and applied without modification, or they are corrected by the addition or subtraction of certain arbitrary amounts called differentials. For instance, rates from New York are applicable to shipments from Boston, but when Baltimore or Philadelphia is the originating point differentials are deducted, the amounts of which vary with the classification of the article shipped and the city at which its transportation begins. Any rate for the transportation of freight from a railway station in the region indicated to any other station situated beyond the

Toronto-Huntington line thus bears a definite relation to the rate applicable to a similar shipment from New York to Chicago.

When a shipment of freight originating east of Buffalo, or any other of the various trunk-line termini, is destined beyond the Mississippi River, to a point not on or near the Pacific coast, the rate is usually determined by adding to the rate to the point at which the Mississippi River is crossed, the ordinary rate from the Mississippi River crossing to the point of final destination. The rate to the Mississippi River crossing used for this purpose may be lower than would be applied to a shipment destined to the same Mississippi River point for local consumption, but it invariably bears a definite relation to the New York and Chicago rate.

Among the circumstances affecting the business of transportation between the Atlantic seaboard and the Middle and Western States, none is more important than the existence of natural and artificial waterways as independent alternative means for moving commodities. A portion of this report will be devoted to the presentation of facts illustrating the rates from time to time available over these routes; but it is desired here to call attention to the fact that many shipments are sent by railway to Buffalo, Erie, Fairport, or Cleveland, and thence to Duluth, Gladstone, Milwaukee, Chicago, or some other western lake port for local consumption or transshipment to the points of final destination. Rates applicable to such shipments are shown in Tables 17, 18, and 19.

TABLE 17.—*Miscellaneous commodities—average rates, regardless of quantity, in cents per 100 pounds.*

Traffic originating in the region, which may roughly be described as bounded upon the west by the Rocky Mountains and upon the east by the Alleghany Mountains, and moving eastward for consumption in the States along the Atlantic seaboard, or for export, differs materially from that traversing the same railways in a westwardly direction. The great bulk of eastward-bound traffic is made up of a few commodities, principally grain and flour or other food products, the bulk and weight of which, in relation to their value, are much greater than those of the numerous small and comparatively valuable products of eastern and foreign factories which move westward. Consequently, it would not be useful to show rates for the eastern movement of as great a variety of articles as those applicable to westward shipments.

Rates on eastern shipments from Chicago to New York are the basis upon which all rates applied to traffic crossing the line from Toronto to Huntington, in an eastwardly direction, are calculated, the adjustment being made in a manner similar to that adopted for west-bound shipments. Table 23 shows the rates applied to shipments of grain via the all-rail and also via the lake and rail routes from Chicago to New York. Elevator and other transfer charges at Buffalo are not included, though canal tolls are during the period prior to January 1, 1883, the date upon which they were abolished.

Rates on grain from the Mississippi River have been for many years 4 cents per 100 pounds higher than those charged from Chicago, and those applied to shipments originating west of that river are made by adding to the rate from the river the rate from the local station at which each particular shipment originates to the point at which the Mississippi is crossed. Rates to Boston on shipments intended for export are the same as to New York, but 5 cents per 100 pounds is added when the grain is intended for consumption in this country. Two cents per 100 pounds is deducted from the New York rate on shipments destined to Philadelphia for either domestic or foreign consumption, and rates to Baltimore are 1 cent lower than those to Philadelphia. Rates on flour are generally the same as on wheat, the weight of a barrel of flour being assumed to be 200 pounds.

TABLE 23.—Grain—average rates, in cents per bushel.

a Average currency values of gold for specific months used in making reductions.

The data in Tables 26 to 30 do not require comment. They apply to staple commodities between points from, and to which, they move in large quantities and over lines for which they constitute a very important portion of the traffic.

*a* April 5 to September 16, inclusive, rates merely nominal and not considered in average.

*b* September 18 to 30, same.

*c* September 29 to November 3, same.

Tables 31 to 35, inclusive, present averages of charges on articles which move in important quantities in the region between Lake Michigan and the Mississippi River on the east and the Missouri River on the west. Rates between the terminals shown are quite generally used as bases of through rates from and to adjacent local points and distant terminals. For example, the rate to be applied to a shipment from a local point in Kansas to New York City would be made by adding the rate in force from such local point to Kansas City, the rate from Kansas City to St. Louis or other point of crossing the Mississippi River and the rate from the latter point to New York.

TABLE 31.—Miscellaneous commodities—average rates, in cents per 100 pounds.

a Rates subsequent to 1888, in cents per 100 pounds.

b Oats 15 cents.

Tables 36 and 37 contain averages of rates in force, from time to time, between New York and Portland, Oreg., Seattle and Tacoma, Wash., and San Francisco, Oakland, Marysville, Los Angeles, and San Diego, Cal. These data are believed fairly to illustrate the charges applied to transcontinental traffic generally; charges between other points involving shipment across the territory between the Missouri and Mississippi rivers on the east and the Rocky Mountains on the west, having varied somewhat in proportion to those shown. The charges illustrated are said to be conditioned by the strong competition of the carriers operating via Panama and Cape Horn, and are in consequence somewhat lower upon most of the commodities named than those to or from intermediate points in the Pacific coast States. Wherever this relation exists, the usual practice in making rates to the local intermediate points is to add to the rates to the nearest of the terminals the rate from the latter point back to destination. There has been some tendency to apply the rates to terminals to shipments of an increasing number of commodities when destined to intermediate points, and this has resulted in a net reduction which it is not practicable to show in the tables.

TABLE 36.—*Miscellaneous commodities—average rates per 100 pounds.*

c April 23 to June 11, 1894, rate to San Francisco only \$1.70.

## FREIGHT TRAFFIC—CARRIERS ON WATER ROUTES.

Tables 38 to 52 relate to that important portion of the interstate commerce of the United States that is transported on the Erie Canal, the Great Lakes, and the Mississippi River. The rates at which shippers can secure the movement of their traffic over these routes not only determine, to a large extent, the channels of commerce, but also constitute a substantial limitation upon the rates which railway carriers can secure for land transportation.

TABLE 38.—Wheat—average rates, in cents per bushel of 60 pounds. (a)

<sup>a</sup> Average currency values of gold for specific months used in making reductions.<sup>b</sup> April average, 12.81 cents.

Owing to the important bearing of transfer charges and canal tolls, when exacted, upon transportation via the Great Lakes and the Erie Canal, the following statement, showing the average of these charges at Buffalo during each year from 1870 to 1897, inclusive, is inserted:

TABLE 44.—*Elevator charges at Buffalo and tolls on Erie Canal—average rates, in cents per bushel.*

[From reports of Buffalo Merchants' Exchange.]

Year.	Elevator charges. (a)	Tolls.	Year.	Elevator charges. (a)	Tolls.
1870 .....	1.09	2.70	1884 .....	0.875	None.
1871 .....	1.12	2.78	1885 .....	.875	Do.

## PASSENGER TRAFFIC.

The following pages contain statements similar to those relating to freight traffic, which have been already presented. The examination of the data contained in these tables should be preceded by the observation that the substantial similarity among the things compared, which is so material to the successful application of the statistical method, is impossible of attainment when the comparisons are among the charges exacted for moving passengers at widely different periods. The accommodations offered to the traveling public during the years prior to 1870, were greatly inferior to those provided at the present time, and the last three decades have been characterized by an improvement that has been continuous and progressive.

The time required for passage between important cities is now but half, or less than half that formerly consumed, and the safety of passengers has been correspondingly increased. Though it may appear, therefore, in the following tables, that the decrease in the charges for the transportation of passengers has not been as great as that in the charges for freight service, it should be borne in mind that the thing which the traveler purchases with the money paid as fare has varied in his favor in every important element except that of distance. The dollar with which a man purchases transportation in a train moving at a modern rate of speed, provided with air brakes and automatic couplers, with coaches of modern construction, over a track composed

of Bessemer steel rails, weighing 100 pounds to the yard, on a line provided with block signaling apparatus, purchases vastly more than a dollar paid for transportation under the conditions which existed but one or two decades ago.

Table 54 contains data which correspond to those relating to freight traffic in Table 1. The scheme of tabulation followed in connection with Table 1, and fully explained in the comments relating thereto, was also used in preparing this table, and the data in the latter are subject to limitations similar to those stated as applicable to those in the former table.

TABLE 54.—*Volume of traffic, efficiency of service, and earnings.*

Year.	Average number carried per mile of road operated.	Average number carried 1 mile per mile of road operated.	Average mileage of passenger trains per mile of road operated.	Average number carried per 1,000 miles run by passenger trains.	Average number carried 1 mile per mile run by passenger trains.	Average distance carried per passenger.	Average revenue from passengers per mile of road operated. (a)	Average revenue from passengers per mile run by passenger trains. (a)	Average revenue from each passenger carried.	Average revenue from each passenger per mile carried.

a Revenue from mail and express services not included.

Table 55 shows the number of miles of railway operated in the United States during each year from 1867 to 1887 inclusive, and the proportion of such mileage represented by the averages under similar headings in Table 54:

TABLE 55.—Per cent of the railway mileage of the United States represented by averages under similar headings in Table 54.

Year.	Number of miles operated.	Average number carried per mile of road operated.	Average number carried 1 mile per mile of road operated. It is significant that the figures in Table 54 do not indicate an increase in the volume of passenger movement per mile of line corresponding to the increase in the volume of freight traffic shown in Table 1, though it is impossible to say how far the apparent decrease is attributable to the probably greater than average volume of traffic carried by the lines which it was possible to include in the tabulations for the earlier years.

It will be noted that the average revenue for each passenger per mile carried increased somewhat after 1867, the average for 1871 being the highest shown. No considerable decrease appears to have taken place until after 1878, from which year the downward tendency has been without substantial interruption.

Table 56 contains average rates per passenger per mile for a large number of railways, and is followed by other tables believed to be illustrative of the general trend of charges for passenger service which do not require especial comment.

TABLE 56.—Average rates per passenger per mile, in cents, miscellaneous railroads.

## THE DECLINE IN PRICES AND RATES COMPARED.

While this report has been carefully restricted to the presentation of facts, leaving the explanation of those facts and inductions, no matter how fully warranted, to those who care to study the data here arranged and classified, the special facilities enjoyed by this office justify, if they do not demand, the presentation of a few facts which, though not of a primary nature, could not be so readily compiled elsewhere and may be suggestive to those who wish to investigate further the relation between the decline in prices and that in railway rates.

Table 70 shows the relation between the yearly average farm prices of each of the principal crops except cotton, the fluctuations of which during the period immediately subsequent to the war for the preservation of the Union, were too violent to permit its use as a basis of comparison, and the average of the prices of the same products for the six years 1867 to 1872, inclusive. The last column shows similar relations for the average rate per ton of freight per mile charged by the railways of the United States as shown in Table 1. This table was made by regarding the average of the prices of each commodity and of railway charges for the six years taken as a basis as 100 per cent and finding the percentage of the average for each year upon that base.

The substantial regularity of the decline in railway rates is especially notable, as is also the fact that for any series of years after the earliest, which may be selected, it is greater than the decline in the price of any crop. Including 1896, the reduction in the price of only one crop, and that of minor importance, is seen to have been greater than that in freight rates, while the decline in the latter has been 23 per cent greater than in the price of wheat and 12 per cent greater than in that of hay.

TABLE 70.—Percentages of yearly averages on average for the six years 1867 to 1872, inclusive.

Year.	Farm prices.									Freight rate per ton per mile.

Table 71 presents comparisons of the average rates charged for transporting wheat and corn from Chicago to New York via the Great Lakes and the Erie Canal during each year from 1867 to 1897, inclusive, with the average export prices of those cereals during the same years. In the third and sixth columns there is shown for each year the number of bushels which could be carried for the export price of one bushel of each of these grains.

Briefly summarized, this table shows a much more rapid decline in the charges for transportation than in the prices of the commodities named. For example, with regard to wheat in 1867, the equivalent of one bushel out of every 5.77 bushels received at New York for export was taken by the carriers as compensation for the transportation service east of Chicago. Though fluctuations have been wide, it does not appear that the rate has been relatively so high during any subsequent year, while during 1897 the value of only one bushel out of 17.24 was required to meet transportation charges. The export prices shown are from the reports of the Bureau of Statistics of the Treasury Department and the rates from Tables 39 and 42 of this report.

TABLE 71.—Wheat and corn—export prices and transportation rates compared.

In the next and concluding table, prices of anthracite coal at Philadelphia are compared with the rates per ton per mile on coal charged by the Lehigh Valley Railway, and the figures of the third and sixth columns show the extreme distance which a ton might have been carried in each year before the transportation charges would have added to the original price more than the price of a ton in Philadelphia. The prices used are from the Statistical Abstract of the Treasury Department and the average rates from Table 10 of this report. Table 72 also shows a decline in the transportation rates to which it refers which is much greater than that in the prices of the commodity to which they are applied.

TABLE 72.—*Prices of anthracite coal compared with rates on coal.*

(Average prices in dollars per ton of 2,240 pounds; rates in cents per ton of 2,000 pounds per mile.)
